20 One-Liners to Remember

Quick-fire facts for last-minute revision.

- 1 Financial Statement Analysis converts raw accounting data into decision-useful information for lenders.**
It turns balance sheet, P&L and cash flow figures into judgments a banker can act on.
- 2 The balance sheet is a stock concept showing what a firm owns and owes on a given date.**
It is a snapshot of assets, liabilities and net worth at one point in time, not over a period.
- 3 The profit and loss account is a flow concept showing how much a firm earned over a period.**
Unlike the balance sheet, it measures income and expenses across an accounting period.
- 4 The cash flow statement reconciles accrual profit with actual cash movements.**
It splits cash movement into operating, investing and financing activities to show real liquidity.
- 5 ABFM examiners frame Financial Statement Analysis questions around liquidity, solvency and profitability.**
These three angles test whether a firm can pay short-term dues, survive long-term debt, and use capital productively.

6 Horizontal analysis compares each line item across two or more periods in rupees and percentage terms.

It reveals trends such as sales growth versus faster-rising interest cost.

7 Vertical or common-size analysis expresses each line as a percentage of a base like total assets or net sales.

Removing the size effect lets a banker compare a small firm with a large one on the same footing.

8 Trend analysis indexes a base year to 100 and tracks movement over several years.

It highlights structural change in a firm's financials over a longer horizon.

9 The current ratio equals current assets divided by current liabilities.

Banks traditionally treat about 1.33:1 as the working-capital benchmark for this ratio.

10 The quick ratio equals current assets minus inventory, divided by current liabilities.

It tests liquidity without relying on selling stock, with a rough norm of 1:1.

11 The debt-equity ratio equals total debt divided by net worth and measures long-term gearing.

A lower debt-equity ratio generally signals safer long-term solvency for a borrower.

12 Interest coverage ratio equals EBIT divided by interest expense.

It shows how comfortably a firm's earnings can service its interest obligations.

13 Return on equity equals net profit divided by net worth.

It measures the return earned on shareholders' invested capital.

14 DSCR equals PAT plus depreciation plus term-loan interest, divided by term-loan interest plus instalment.

Lenders use the Debt Service Coverage Ratio to judge a project's ability to repay term debt.

15 A DSCR above 1.5 is generally considered comfortable in project finance lending.

It indicates cash generation comfortably exceeds the debt-servicing obligation.

16 DuPont analysis decomposes return on equity into net profit margin, asset turnover and equity multiplier.

It separates whether high ROE comes from genuine profitability or from heavy leverage.

17 Window dressing can involve repaying creditors just before year-end to inflate the current ratio.

Analysts must watch for such temporary balance-sheet adjustments before trusting a reported ratio.

- 18** **Reported profit is based on accrual accounting and is not the same as cash in hand.**

A firm can show rising profit while its actual cash position deteriorates.

- 19** **The 1.33:1 current ratio benchmark used in bank lending traces back to the Tandon and Chore committee norms.**

These older committee recommendations still shape working-capital assessment practice.

- 20** **A disciplined exam answer follows the sequence compute, interpret, then state the limitation.**

This three-step structure converts a memorised ratio formula into analytical judgement that examiners reward.
